Flow Control

- Flow control refers to a set of procedures used to restrict the amount of data that the sender can send before waiting for acknowledgment.
- In most protocols, flow control is a set of procedures that tells the sender how much data it can transmit before it must wait for an acknowledgment from the receiver.
- The flow of data must not be allowed to overwhelm the receiver.
- Any receiving device has a limited speed at which it can process incoming data and a limited amount of memory in which to store incoming data.
- The receiving device must be able to inform the sending device before those limits are reached and to request that the transmitting device send fewer frames or stop temporarily.

Flow Control

- Incoming data must be checked and processed before they can be used.
- The rate of such processing is often slower than the rate of transmission.
- For this reason, each receiving device has a block of memory, called a buffer, reserved for storing incoming data until they are processed.
- If the buffer begins to fill up, the receiver must be able to tell the sender to halt transmission until it is once again able to receive.

Types Of Flow Control

Access Control

08/28/2025

Computer Network

By: Mr. Almas Sheikh

Access Control

- Access Control is a mechanism that controls the access of stations to the transmission link.
- Broadcast links require the access control.
- This is because the link is shared among several stations.
- To prevent the occurrence of collision or if the collision occurs.

Access Control

- We can consider the data link layer as two sub layers.
- The upper sub layer is responsible for data link control, and the lower sub layer is responsible for resolving access to the shared media.
- If the channel is dedicated, we do not need the lower sub layer.
- The situation is similar for multipoint networks.
- Many formal protocols have been devised to handle access to a shared little
